

## JAVA NOTES

### What is Java

Java is a **programming language** and a **platform**. Java is a high level, robust, secured and object-oriented programming (oops) language.

**Platform:** Any hardware or software environment in which a program runs , is known as a platform. Since Java has its own runtime environment (JRE) and API, it is called platform.

### Why is java Platform Independent

A platform is the hardware or software environment in which a program runs.

There are two types of platforms software-based and hardware-based. **Java provides software-based platform.**

The Java platform differs from most other platforms in the sense that it is a software-based platform that runs on the top of other hardware-based platforms. It has two components:

1. Runtime Environment
2. API(Application Programming Interface)

Java code can be run on multiple platforms e.g. Windows, Linux, Sun Solaris, Mac/OS etc. Java code is compiled by the compiler and converted into **bytecode**. This bytecode is a platform-independent code because it can be run on multiple platforms i.e. Write Once and Run Anywhere(WORA).

### Overview of java

- **Object Oriented** – In Java, everything is an Object. Java can be easily extended since it is based on the Object model.
- **Platform Independent** – Unlike many other programming languages including C and C++, when Java is compiled, it is not compiled into platform specific machine, rather into platform independent byte code. This byte code is distributed over the web and interpreted by the Virtual Machine (JVM) on whichever platform it is being run on.
- **Simple** – Java is designed to be easy to learn. If you understand the basic concept of OOP Java, it would be easy to master.
- **Secure** – With Java's secure feature it enables to develop virus-free. Authentication techniques are based on public-key encryption.
- **Architecture-neutral** – Java compiler generates an architecture-neutral object file format, which makes the compiled code executable on many processors, with the presence of Java runtime system.

- **Multithreaded** – With Java's multithreaded feature it is possible to write programs that can perform many tasks simultaneously. This design feature allows the developers to construct interactive applications that can run smoothly.

## Oops features-(object oriented programming concepts/system)

1. **Object**=Any entity that has state and behavior is known as an object. For example: chair, pen, table, keyboard, bike etc. It can be physical and logical.
2. **Class=Collection of objects** is called class. It is a logical entity.
3. **Inheritance=When one object acquires all the properties and behaviours of parent object** i.e. known as inheritance. It provides code reusability. It is used to achieve runtime polymorphism.

**Polymorphism**=When **one task is performed by different ways** i.e. known as polymorphism. For example: to convince the customer differently, to draw something e.g. shape or rectangle etc.

In java, we use method overloading and method overriding to achieve polymorphism.

Another example can be to speak something e.g. cat speaks meow, dog barks woof etc

**4.Abstraction=Hiding internal details and showing functionality** is known as abstraction. For example: phone call, we don't know the internal processing.

In java, we use abstract class and interface to achieve abstraction.

**5.Encapsulation=Binding (or wrapping) code and data together into a single unit is known as encapsulation.** For example: capsule, it is wrapped with different medicines.

A java class is the example of encapsulation. Java bean is the fully encapsulated class because all the data members are private here.

**6.Data hiding**=by access specifier-default,public,private,protected.

## C++ vs Java

There are many differences and similarities between C++ programming language and Java. A list of top differences between C++ and Java are given below:

Comparison Index	C++	Java
Platform-independent	C++ is platform-dependent.	Java is platform-independent.

Mainly used for	C++ is mainly used for system programming.	Java is mainly used for application programming. It is widely used in window, web-based, enterprise and mobile applications.
Goto	C++ supports goto statement.	Java doesn't support goto statement.
Multiple inheritance	C++ supports multiple inheritance.	Java doesn't support multiple inheritance through class. It can be achieved by interfaces in java.
Operator Overloading	C++ supports operator overloading.	Java doesn't support operator overloading.
Pointers	C++ supports pointers. You can write pointer program in C++.	Java supports pointer internally. But you can't write the pointer program in java. It means java has restricted pointer support in java.
Compiler and Interpreter	C++ uses compiler only.	Java uses compiler and interpreter both.
Call by Value and Call by reference	C++ supports both call by value and call by reference.	Java supports call by value only. There is no call by reference in java.
Structure and Union	C++ supports structures and unions.	Java doesn't support structures and unions.
Thread Support	C++ doesn't have built-in support for threads. It relies on third-party libraries for thread support.	Java has built-in thread support.
Documentation comment	C++ doesn't support documentation comment.	Java supports documentation comment (/** ... */) to create documentation for java source code.
Virtual Keyword	C++ supports virtual keyword so that we can decide whether or not override a function.	Java has no virtual keyword. We can override all non-static methods by default. In other words, non-static methods are virtual by default.
unsigned right shift >>>	C++ doesn't support >>> operator.	Java supports unsigned right shift >>> operator that fills zero at the top for the negative numbers. For positive numbers, it works same like >> operator.
Inheritance Tree	C++ creates a new inheritance tree always.	Java uses single inheritance tree always because all classes are the child of Object class in java. Object class is the root of inheritance tree in java.

# JVM (Java Virtual Machine)

JVM (Java Virtual Machine) is an abstract machine. It is a specification that provides runtime environment in which java bytecode can be executed.

JVMs are available for many hardware and software platforms (i.e. JVM is platform dependent).

## What is JVM

It is:

1. **A specification** where working of Java Virtual Machine is specified. But implementation provider is independent to choose the algorithm. Its implementation has been provided by Sun and other companies.
2. **An implementation** Its implementation is known as JRE (Java Runtime Environment).
3. **Runtime Instance** Whenever you write java command on the command prompt to run the java class, an instance(object) of JVM is created.

## What it does

The JVM performs following operation:

- Loads code
- Verifies code
- Executes code
- Provides runtime environment

JVM provides definitions for the:

- Memory area
- Class file format
- Register set
- Garbage-collected heap
- Fatal error reporting etc.

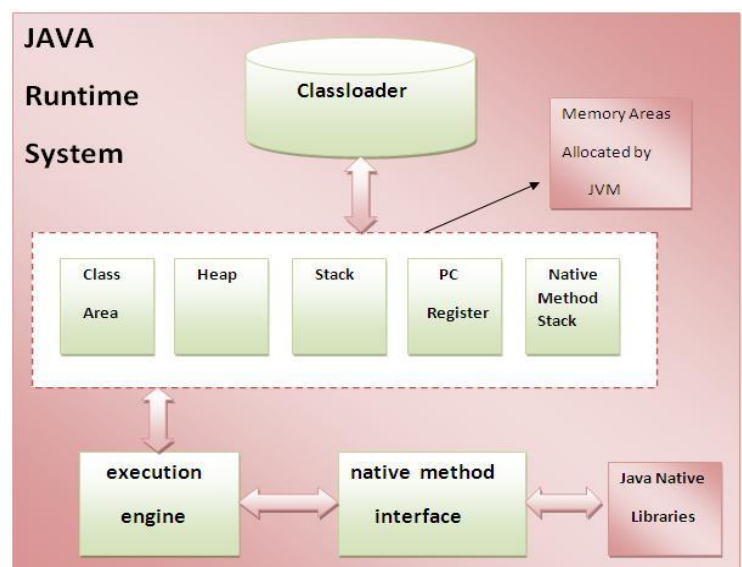

## internal Architecture of JVM

Let's understand the internal architecture of JVM. It contains classloader, memory area, execution engine etc.

### 1) Classloader

ClassLoader is a subsystem of JVM that is used to load class files.

### 2) Class(Method) Area

Class(Method) Area stores per-class structures such as the runtime constant pool, field and method data, the code for methods.

### 3) Heap

It is the runtime data area in which objects are allocated.

### 4) Stack

Java Stack stores frames. It holds local variables and partial results, and plays a part in method invocation and return.

Each thread has a private JVM stack, created at the same time as thread.

A new frame is created each time a method is invoked. A frame is destroyed when its method invocation completes.

### 5) Program Counter Register

PC (program counter) register. It contains the address of the Java virtual machine instruction currently being executed.

### 6) Native Method Stack

It contains all the native methods used in the application.

### 7) Execution Engine

It contains:

#### 1) A virtual processor

#### 2) **Interpreter:** Read bytecode stream then execute the instructions.

**3) Just-In-Time(JIT) compiler:** It is used to improve the performance. JIT compiles parts of the byte code that have similar functionality at the same time, and hence reduces the amount of time needed for compilation. Here the term ?compiler? refers to a translator from the instruction set of a Java virtual machine (JVM) to the instruction set of a specific CPU.

## JRE

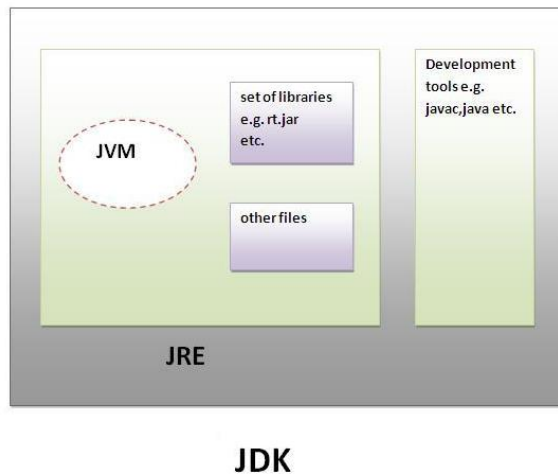

JRE is an acronym for Java Runtime Environment. It is used to provide runtime environment. It is the implementation of JVM. It physically exists. It contains set of libraries + other files that JVM uses at runtime.

Implementation of JVMs are also actively released by other companies besides Sun Micro Systems.

## JDK

JDK is an acronym for Java Development Kit. It physically exists. It contains JRE + development tools.

## How to set path in Java

The path is required to be set for using tools such as javac, java etc.

If you are saving the java source file inside the jdk/bin directory, path is not required to be set because all the tools will be available in the current directory.

But If you are having your java file outside the jdk/bin folder, it is necessary to set path of JDK.

There are 2 ways to set java path:

1. temporary
2. permanent

### 1) How to set Temporary Path of JDK in Windows

To set the temporary path of JDK, you need to follow following steps:

- Open command prompt
- copy the path of jdk/bin directory
- write in command prompt: set path=copied\_path

For Example:

```
set path=C:\Program Files\Java\jdk1.6.0_23\bin
```

### 2) How to set Permanent Path of JDK in Windows

For setting the permanent path of JDK, you need to follow these steps:

- Go to MyComputer properties -> advanced tab -> environment variables -> new tab of user variable -> write path in variable name -> write path of bin folder in variable value -> ok -> ok -> ok

## Setting Java Path in Linux OS

Setting the path in Linux OS is same as setting the path in the Windows OS. But here we use export tool rather than set. Let's see how to set path in Linux OS:

```
export PATH=$PATH:/home/jdk1.6.01/bin/
```

Here, we have installed the JDK in the home directory under Root (/home).

## Java Variables

Following are the types of variables in Java –

- **Local Variables**-Variables defined inside methods, constructors or blocks are called local variables. The variable will be declared and initialized within the method and the variable will be destroyed when the method has completed.
- **Class Variables** - Class variables are variables declared within a class, outside any method, with the static keyword.
- **Instance Variables** - Instance variables are variables within a class but outside any method. These variables are initialized when the class is instantiated. Instance variables can be accessed from inside any method, constructor or blocks of that particular class.

## Constructors

When discussing about classes, one of the most important sub topic would be constructors. Every class has a constructor. If we do not explicitly write a constructor for a class, the Java compiler builds a default constructor for that class.

Each time a new object is created, at least one constructor will be invoked. The main rule of constructors is that they should have the same name as the class. A class can have more than one constructor.

Two types-default/no-args constructor and parameterized constructor

## Difference between constructor and method in java

There are many differences between constructors and methods. They are given below.

Java Constructor	Java Method
Constructor is used to initialize the state of an object.	Method is used to expose behaviour of an object.
Constructor must not have return type.	Method must have return type.
Constructor is invoked implicitly.	Method is invoked explicitly.
The java compiler provides a default constructor if you don't have any	Method is not provided by compiler in any

constructor.	case.
Constructor name must be same as the class name.	Method name may or may not be same as class name.

## Java Scanner class

There are various ways to read input from the keyboard, the `java.util.Scanner` class is one of them.

The **Java Scanner** class breaks the input into tokens using a delimiter that is whitespace by default. It provides many methods to read and parse various primitive values.

Java Scanner class is widely used to parse text for string and primitive types using regular expression.

Java Scanner class extends `Object` class and implements `Iterator` and `Closeable` interfaces.

### Commonly used methods of Scanner class

Method	Description
<code>public String next()</code>	it returns the next token from the scanner.
<code>public String nextLine()</code>	it moves the scanner position to the next line and returns the value as a string.
<code>public byte nextByte()</code>	it scans the next token as a byte.
<code>public short nextShort()</code>	it scans the next token as a short value.
<code>public int nextInt()</code>	it scans the next token as an int value.
<code>public long nextLong()</code>	it scans the next token as a long value.
<code>public float nextFloat()</code>	it scans the next token as a float value.
<code>public double nextDouble()</code>	it scans the next token as a double value.

## What is an object in Java

An entity that has **state and behavior** is known as an object e.g., chair, bike, marker, pen, table, car, etc. It can be physical or logical (tangible and intangible). The example of an intangible object is the banking system.

Pen:name color for writing purpose

An object has three characteristics:

- **State:** represents the data (value) of an object.
- **Behavior:** represents the behavior (functionality) of an object such as deposit, withdraw, etc.
- **Identity:** An object identity is typically implemented via a unique ID. The value of the ID is not visible to the external user. However, it is used internally by the JVM to identify each object uniquely.

For Example, Pen is an object. Its name is link; color is blue, known as its state. It is used to write, so writing is its behavior.

**An object is an instance of a class.** A class is a template or blueprint from which objects are created. So, an object is the instance(result) of a class.

### **Object Definitions:**

- An object is *a real-world entity*.
- An object is *a runtime entity*.
- The object is *an entity which has state and behavior*.
- The object is *an instance of a class*.

## **What is a class in Java**

A class is a group of objects which have common properties. It is a template or blueprint from which objects are created. It is a logical entity. It can't be physical.

A class in Java can contain:

- **Fields**
- **Methods**
- **Constructors**
- **Blocks**
- **Nested class and interface**

## Instance variable in Java

A variable which is created inside the class but outside the method is known as an instance variable. Instance variable doesn't get memory at compile time. It gets memory at runtime when an object or instance is created. That is why it is known as an instance variable.

---

## Method in Java

In Java, a method is like a function which is used to expose the behavior of an object.

### ***Advantage of Method***

- Code Reusability
- Code Optimization

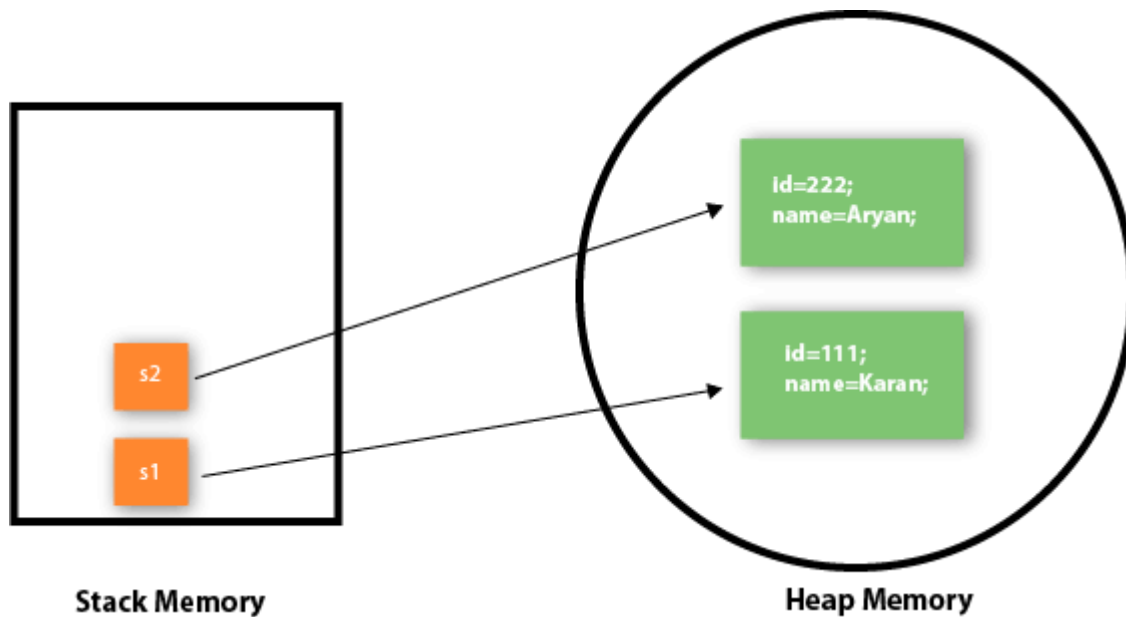

## new keyword in Java

The new keyword is used to allocate memory at runtime. All objects get memory in Heap memory area.

## 3 Ways to initialize object

There are 3 ways to initialize object in Java.

1. By reference variable
2. By method
3. By constructor

As you can see in the above figure, object gets the memory in heap memory area. The reference variable refers to the object allocated in the heap memory area. Here, s1 and s2 both are reference variables that refer to the objects allocated in memory.

## What are the different ways to create an object in Java?

There are many ways to create an object in java. They are:

- By new keyword
- By newInstance() method
- By clone() method
- By deserialization
- By factory method etc.

## Anonymous object

Anonymous simply means nameless. An object which has no reference is known as an anonymous object. It can be used at the time of object creation only.

If you have to use an object only once, an anonymous object is a good approach. For example:

1. **new** Calculation();//anonymous object

Calling method through a reference:

1. Calculation c=**new** Calculation();
2. c.fact(5);

Calling method through an anonymous object

```
new Calculation().fact(5);  
class Calculation{  
    void fact(int n){  
        int fact=1;  
        for(int i=1;i<=n;i++){  
            fact=fact*i;  
        }  
        System.out.println("factorial is "+fact);  
    }  
    public static void main(String args[]){  
        new Calculation().fact(5);//calling method with anonymous object  
    }  
}
```

## Creating multiple objects by one type only

We can create multiple objects by one type only as we do in case of primitives.

Initialization of primitive variables:

1. **int** a=10, b=20;

Initialization of reference variables:

1. Rectangle r1=**new** Rectangle(), r2=**new** Rectangle();//creating two objects

ClassCreationExml obj=new ClassCreationExml(); //default constructor,it will initialize instance variable with default value

int=0 heap

float=0.0

String=null

ClassCreationExml obj1=new ClassCreationExml();

Syntax:

Visibility return type(output) method\_name(parameter list)

{

//task

}

Add=add two integer number

public int addition(int a,int b)

{

Return a+b; return 30

}

```
int result=Obj.addition(10,20);  
public void printMessage()  
{  
System.out.println("hi");  
}
```

## Java Variables

A variable is a container which holds the value while the Java program is executed. A variable is assigned with a data type.

Variable is a name of memory location. There are three types of variables in java: local, instance and static.

There are two types of data types in Java: primitive and non-primitive.

---

## Variable

A variable is the name of a reserved area allocated in memory. In other words, it is a name of the memory location. It is a combination of "vary + able" which means its value can be changed.

1. `int data=50;` // Here data is variable

## Types of Variables

There are three types of variables in [Java](#):

- local variable
- instance variable
- static variable

# Types of Variables

## **1) Local Variable**

A variable declared inside the body of the method is called local variable. You can use this variable only within that method and the other methods in the class aren't even aware that the variable exists.

A local variable cannot be defined with "static" keyword.

## **2) Instance Variable**

A variable declared inside the class but outside the body of the method, is called an instance variable. It is not declared as static.

It is called an instance variable because its value is instance-specific and is not shared among instances.

### 3) Static variable

A variable that is declared as static is called a static variable. It cannot be local. You can create a single copy of the static variable and share it among all the instances of the class. Memory allocation for static variables happens only once when the class is loaded in the memory.

### Example to understand the types of variables in java

```
1. public class A
2. {
3.     static int m=100;//static variable
4.     void method()
5.     {
6.         int n=90;//local variable
7.     }
8.     public static void main(String args[])
9.     {
10.        int data=50;//instance variable
11.    }
12. }//end of class
```

### Java Variable Example: Add Two Numbers

```
1. public class Simple{
2.     public static void main(String[] args){
3.         int a=10;
4.         int b=10;
5.         int c=a+b;
6.         System.out.println(c);
7.     }
8. }
```

## Data Types in Java

Data types specify the different sizes and values that can be stored in the variable. There are two types of data types in Java:

1. **Primitive data types:** The primitive data types include boolean, char, byte, short, int, long, float and double.
2. **Non-primitive data types:** The non-primitive data types include [Classes](#), [Interfaces](#), and [Arrays](#).

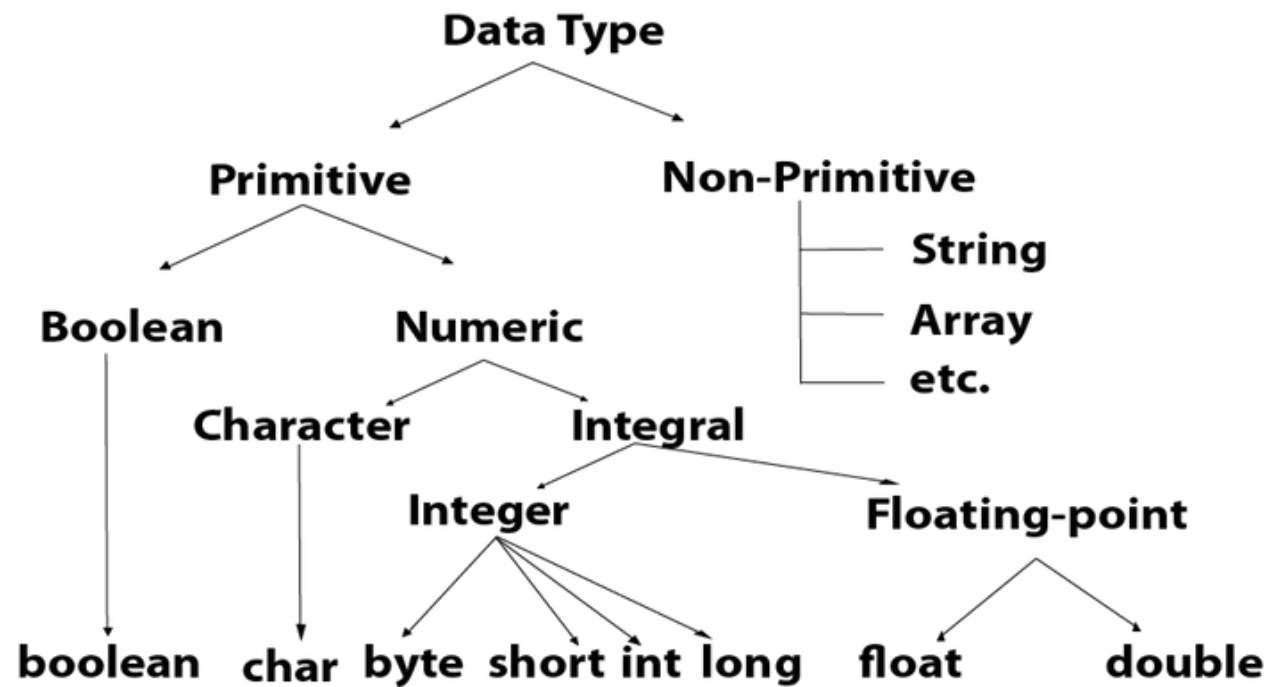

## Java Primitive Data Types

In Java language, primitive data types are the building blocks of data manipulation. These are the most basic data types available in [Java language](#).

Java is a statically-typed programming language. It means, all [variables](#) must be declared before its use. That is why we need to declare variable's type and name.

There are 8 types of primitive data types:

- boolean data type
- byte data type
- char data type
- short data type
- int data type
- long data type
- float data type
- double data type

Data Type	Default Value	Default size
boolean	false	1 bit
char	'\u0000'	2 byte
byte	0	1 byte
short	0	2 byte
int	0	4 byte
long	0L	8 byte
float	0.0f	4 byte
double	0.0d	8 byte

## Boolean Data Type

The Boolean data type is used to store only two possible values: true and false. This data type is used for simple flags that track true/false conditions.

The Boolean data type specifies one bit of information, but its "size" can't be defined precisely.

### Example:

1. Boolean one = **false**

## Byte Data Type

The byte data type is an example of primitive data type. It is an 8-bit signed two's complement integer. Its value-range lies between -128 to 127 (inclusive). Its minimum value is -128 and maximum value is 127. Its default value is 0.

The byte data type is used to save memory in large arrays where the memory savings is most required. It saves space because a byte is 4 times smaller than an integer. It can also be used in place of "int" data type.

### Example:

1. **byte** a = **10**, **byte** b = **-20**

## Short Data Type

The short data type is a 16-bit signed two's complement integer. Its value-range lies between -32,768 to 32,767 (inclusive). Its minimum value is -32,768 and maximum value is 32,767. Its default value is 0.

The short data type can also be used to save memory just like byte data type. A short data type is 2 times smaller than an integer.

### Example:

1. **short** s = **10000**, **short** r = **-5000**

## Int Data Type

The int data type is a 32-bit signed two's complement integer. Its value-range lies between  $-2,147,483,648$  ( $-2^{31}$ ) to  $2,147,483,647$  ( $2^{31} - 1$ ) (inclusive). Its minimum value is  $-2,147,483,648$  and maximum value is  $2,147,483,647$ . Its default value is 0.

The int data type is generally used as a default data type for integral values unless if there is no problem about memory.

### Example:

1. `int a = 100000, int b = -200000`

## Long Data Type

The long data type is a 64-bit two's complement integer. Its value-range lies between  $-9,223,372,036,854,775,808$  ( $-2^{63}$ ) to  $9,223,372,036,854,775,807$  ( $2^{63} - 1$ ) (inclusive). Its minimum value is  $-9,223,372,036,854,775,808$  and maximum value is  $9,223,372,036,854,775,807$ . Its default value is 0. The long data type is used when you need a range of values more than those provided by int.

### Example:

1. `long a = 100000L, long b = -200000L`

## Float Data Type

The float data type is a single-precision 32-bit IEEE 754 floating point. Its value range is unlimited. It is recommended to use a float (instead of double) if you need to save memory in large arrays of floating point numbers. The float data type should never be used for precise values, such as currency. Its default value is 0.0F.

### Example:

1. `float f1 = 234.5f`

## Double Data Type

The double data type is a double-precision 64-bit IEEE 754 floating point. Its value range is unlimited. The double data type is generally used for decimal values just like float. The

double data type also should never be used for precise values, such as currency. Its default value is 0.0d.

**Example:**

1. `double` d1 = 12.3

## Char Data Type

The char data type is a single 16-bit Unicode character. Its value-range lies between '\u0000' (or 0) to '\uffff' (or 65,535 inclusive).The char data type is used to store characters.

**Example:**

1. `char` letterA = 'A'

## Why char uses 2 byte in java and what is \u0000 ?

It is because java uses Unicode system not ASCII code system. The \u0000 is the lowest range of Unicode system.

## Unicode System

Unicode is a universal international standard character encoding that is capable of representing most of the world's written languages.

## Why java uses Unicode System?

Before Unicode, there were many language standards:

- **ASCII** (American Standard Code for Information Interchange) for the United States.
- **ISO 8859-1** for Western European Language.
- **KOI-8** for Russian.
- **GB18030 and BIG-5** for chinese, and so on.

## Problem

**This caused two problems:**

1. A particular code value corresponds to different letters in the various language standards.
2. The encodings for languages with large character sets have variable length. Some common characters are encoded as single bytes, other require two or more byte.

## Solution

To solve these problems, a new language standard was developed i.e. Unicode System.

In unicode, character holds 2 byte, so java also uses 2 byte for characters.

**lowest value:** \u0000

**highest value:** \uFFFF

## Java Keywords

Java keywords are also known as reserved words. Keywords are particular words that act as a key to a code. These are predefined words by Java so they cannot be used as a variable or object name or class name.

## List of Java Keywords

A list of Java keywords or reserved words are given below:

1. **abstract:** Java abstract keyword is used to declare an abstract class. An abstract class can provide the implementation of the interface. It can have abstract and non-abstract methods.
2. **boolean:** Java boolean keyword is used to declare a variable as a boolean type. It can hold True and False values only.
3. **break:** Java break keyword is used to break the loop or switch statement. It breaks the current flow of the program at specified conditions.
4. **byte:** Java byte keyword is used to declare a variable that can hold 8-bit data values.
5. **case:** Java case keyword is used with the switch statements to mark blocks of text.
6. **catch:** Java catch keyword is used to catch the exceptions generated by try statements. It must be used after the try block only.

7. **char**: Java char keyword is used to declare a variable that can hold unsigned 16-bit Unicode characters
8. **class**: Java class keyword is used to declare a class.
9. **continue**: Java continue keyword is used to continue the loop. It continues the current flow of the program and skips the remaining code at the specified condition.
10. **default**: Java default keyword is used to specify the default block of code in a switch statement.
11. **do**: Java do keyword is used in the control statement to declare a loop. It can iterate a part of the program several times.
12. **double**: Java double keyword is used to declare a variable that can hold 64-bit floating-point number.
13. **else**: Java else keyword is used to indicate the alternative branches in an if statement.
14. **enum**: Java enum keyword is used to define a fixed set of constants. Enum constructors are always private or default.
15. **extends**: Java extends keyword is used to indicate that a class is derived from another class or interface.
16. **final**: Java final keyword is used to indicate that a variable holds a constant value. It is used with a variable. It is used to restrict the user from updating the value of the variable.
17. **finally**: Java finally keyword indicates a block of code in a try-catch structure. This block is always executed whether an exception is handled or not.
18. **float**: Java float keyword is used to declare a variable that can hold a 32-bit floating-point number.
19. **for**: Java for keyword is used to start a for loop. It is used to execute a set of instructions/functions repeatedly when some condition becomes true. If the number of iteration is fixed, it is recommended to use for loop.
20. **if**: Java if keyword tests the condition. It executes the if block if the condition is true.
21. **implements**: Java implements keyword is used to implement an interface.
22. **import**: Java import keyword makes classes and interfaces available and accessible to the current source code.
23. **instanceof**: Java instanceof keyword is used to test whether the object is an instance of the specified class or implements an interface.

24. **int**: Java int keyword is used to declare a variable that can hold a 32-bit signed integer.
25. **interface**: Java interface keyword is used to declare an interface. It can have only abstract methods.
26. **long**: Java long keyword is used to declare a variable that can hold a 64-bit integer.
27. **native**: Java native keyword is used to specify that a method is implemented in native code using JNI (Java Native Interface).
28. **new**: Java new keyword is used to create new objects.
29. **null**: Java null keyword is used to indicate that a reference does not refer to anything. It removes the garbage value.
30. **package**: Java package keyword is used to declare a Java package that includes the classes.
31. **private**: Java private keyword is an access modifier. It is used to indicate that a method or variable may be accessed only in the class in which it is declared.
32. **protected**: Java protected keyword is an access modifier. It can be accessible within the package and outside the package but through inheritance only. It can't be applied with the class.
33. **public**: Java public keyword is an access modifier. It is used to indicate that an item is accessible anywhere. It has the widest scope among all other modifiers.
34. **return**: Java return keyword is used to return from a method when its execution is complete.
35. **short**: Java short keyword is used to declare a variable that can hold a 16-bit integer.
36. **static**: Java static keyword is used to indicate that a variable or method is a class method. The static keyword in Java is mainly used for memory management.
37. **strictfp**: Java strictfp is used to restrict the floating-point calculations to ensure portability.
38. **super**: Java super keyword is a reference variable that is used to refer to parent class objects. It can be used to invoke the immediate parent class method.
39. **switch**: The Java switch keyword contains a switch statement that executes code based on test value. The switch statement tests the equality of a variable against multiple values.
40. **synchronized**: Java synchronized keyword is used to specify the critical sections or methods in multithreaded code.

41. **this:** Java this keyword can be used to refer the current object in a method or constructor.
42. **throw:** The Java throw keyword is used to explicitly throw an exception. The throw keyword is mainly used to throw custom exceptions. It is followed by an instance.
43. **throws:** The Java throws keyword is used to declare an exception. Checked exceptions can be propagated with throws.
44. **transient:** Java transient keyword is used in serialization. If you define any data member as transient, it will not be serialized.
45. **try:** Java try keyword is used to start a block of code that will be tested for exceptions. The try block must be followed by either catch or finally block.
46. **void:** Java void keyword is used to specify that a method does not have a return value.
47. **volatile:** Java volatile keyword is used to indicate that a variable may change asynchronously.
48. **while:** Java while keyword is used to start a while loop. This loop iterates a part of the program several times. If the number of iteration is not fixed, it is recommended to use the while loop.

## Operators in Java

**Operator** in [Java](#) is a symbol that is used to perform operations. For example: +, -, \*, / etc.

There are many types of operators in Java which are given below:

- Unary Operator,
- Arithmetic Operator,
- Shift Operator,
- Relational Operator,
- Bitwise Operator,
- Logical Operator,
- Ternary Operator and
- Assignment Operator.

# Java Operator Precedence

Operator Type	Category	Precedence
Unary	postfix	<code>expr++ expr--</code>
	prefix	<code>++expr --expr +expr -expr ~ !</code>
Arithmetic	multiplicative	<code>* / %</code>
	additive	<code>+ -</code>
Shift	shift	<code>&lt;&lt; &gt;&gt; &gt;&gt;&gt;</code>
Relational	comparison	<code>&lt; &gt; &lt;= &gt;= instanceof</code>
	equality	<code>== !=</code>
Bitwise	bitwise AND	<code>&amp;</code>
	bitwise exclusive OR	<code>^</code>
	bitwise inclusive OR	<code> </code>
Logical	logical AND	<code>&amp;&amp;</code>
	logical OR	<code>  </code>
Ternary	ternary	<code>? :</code>
Assignment	assignment	<code>= += -= *= /= %= &amp;= ^=  = &lt;&lt;= &gt;&gt;= &gt;&gt;&gt;=</code>

## Java Unary Operator

The Java unary operators require only one operand. Unary operators are used to perform various operations i.e.:

- incrementing/decrementing a value by one
- negating an expression
- inverting the value of a boolean

### Java Unary Operator Example: ++ and --

1. **public class** OperatorExample{
2. **public static void** main(String args[]){
3. **int** x=10;
4. System.out.println(x++);*//10 (11)*
5. System.out.println(++x);*//12*
6. System.out.println(x--);*//12 (11)*
7. System.out.println(--x);*//10*
8. }}

#### Output:

```
10
12
12
10
```

### Java Unary Operator Example 2: ++ and --

1. **public class** OperatorExample{
2. **public static void** main(String args[]){
3. **int** a=10;
4. **int** b=10;
5. System.out.println(a++ + ++a);*//10+12=22*
6. System.out.println(b++ + b++);*//10+11=21*
- 7.
8. }}

#### Output:

```
22
```

## Java Unary Operator Example: ~ and !

1. **public class** OperatorExample{
2. **public static void** main(String args[]){
3. **int** a=10;
4. **int** b=-10;
5. **boolean** c=true;
6. **boolean** d=false;
7. System.out.println(~a);//-11 (minus of total positive value which starts from 0)
8. System.out.println(~b);//9 (positive of total minus, positive starts from 0)
9. System.out.println(!c);//false (opposite of boolean value)
10. System.out.println(!d);//true
11. }}

### Output:

```
-11
9
false
true
```

## Java Arithmetic Operators

Java arithmetic operators are used to perform addition, subtraction, multiplication, and division. They act as basic mathematical operations.

## Java Arithmetic Operator Example

1. **public class** OperatorExample{
2. **public static void** main(String args[]){
3. **int** a=10;
4. **int** b=5;
5. System.out.println(a+b);//15
6. System.out.println(a-b);//5
7. System.out.println(a\*b);//50
8. System.out.println(a/b);//2
9. System.out.println(a%b);//0
10. }}

### Output:

```
15
5
50
2
0
```

## Java Arithmetic Operator Example: Expression

1. **public class** OperatorExample{
2. **public static void** main(String args[]){
3. System.out.println(**10\*10/5+3-1\*4/2**);
4. }}

### Output:

```
21
```

## Java Left Shift Operator

The Java left shift operator << is used to shift all of the bits in a value to the left side of a specified number of times.

## Java Left Shift Operator Example

1. **public class** OperatorExample{
2. **public static void** main(String args[]){
3. System.out.println(**10<<2**);**//10\*2^2=10\*4=40**
4. System.out.println(**10<<3**);**//10\*2^3=10\*8=80**
5. System.out.println(**20<<2**);**//20\*2^2=20\*4=80**
6. System.out.println(**15<<4**);**//15\*2^4=15\*16=240**
7. }}

### Output:

```
40
80
80
240
```

## Java Right Shift Operator

The Java right shift operator >> is used to move the value of the left operand to right by the number of bits specified by the right operand.

## Java Right Shift Operator Example

1. **public** OperatorExample{
2. **public static void** main(String args[]){
3. System.out.println(10>>2);*//10/2^2=10/4=2*
4. System.out.println(20>>2);*//20/2^2=20/4=5*
5. System.out.println(20>>3);*//20/2^3=20/8=2*
6. }}

**Output:**

```
2
5
2
```

## Java Shift Operator Example: >> vs >>>

1. **public class** OperatorExample{
2. **public static void** main(String args[]){
3. *//For positive number, >> and >>> works same*
4. System.out.println(20>>2);
5. System.out.println(20>>>2);
6. *//For negative number, >>> changes parity bit (MSB) to 0*
7. System.out.println(-20>>2);
8. System.out.println(-20>>>2);
9. }}

**Output:**

```
5
5
-5
1073741819
```

## Java AND Operator Example: Logical && and Bitwise &

The logical && operator doesn't check the second condition if the first condition is false. It checks the second condition only if the first one is true.

The bitwise & operator always checks both conditions whether first condition is true or false.

1. **public class** OperatorExample{
2. **public static void** main(String args[]){
3. **int** a=10;
4. **int** b=5;
5. **int** c=20;
6. System.out.println(a<b&&a<c);//false && true = false
7. System.out.println(a<b&a<c);//false & true = false
8. }}

#### Output:

```
false
false
```

### Java AND Operator Example: Logical && vs Bitwise &

1. **public class** OperatorExample{
2. **public static void** main(String args[]){
3. **int** a=10;
4. **int** b=5;
5. **int** c=20;
6. System.out.println(a<b&&a++<c);//false && true = false
7. System.out.println(a);//10 because second condition is not checked
8. System.out.println(a<b&a++<c);//false && true = false
9. System.out.println(a);//11 because second condition is checked
10. }}

#### Output:

```
false
10
false
11
```

### Java OR Operator Example: Logical || and Bitwise |

The logical || operator doesn't check the second condition if the first condition is true. It checks the second condition only if the first one is false.

The bitwise | operator always checks both conditions whether first condition is true or false.

1. **public class** OperatorExample{
2. **public static void** main(String args[]){
3. **int** a=10;
4. **int** b=5;
5. **int** c=20;
6. System.out.println(a>b||a<c);//true || true = true
7. System.out.println(a>b|a<c);//true | true = true
8. **//|| vs |**
9. System.out.println(a>b||a++<c);//true || true = true
10. System.out.println(a);//10 because second condition is not checked
11. System.out.println(a>b|a++<c);//true | true = true
12. System.out.println(a);//11 because second condition is checked
13. }}

#### Output:

```
true
true
true
10
true
11
```

## Java Ternary Operator

Java Ternary operator is used as one line replacement for if-then-else statement and used a lot in Java programming. It is the only conditional operator which takes three operands.

## Ternary Operator

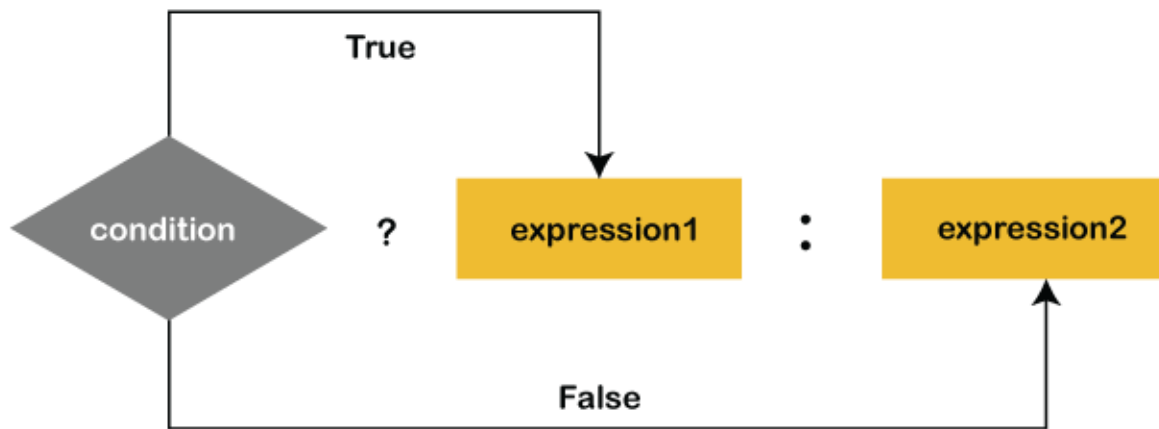

The meaning of **ternary** is composed of three parts. The **ternary operator (? :)** consists of three operands. It is used to evaluate Boolean expressions. The operator decides which value will be assigned to the variable. It can be used instead of the if-else statement. It makes the code much more easy, readable, and shorter.

**Note:** Every code using an if-else statement cannot be replaced with a ternary operator.

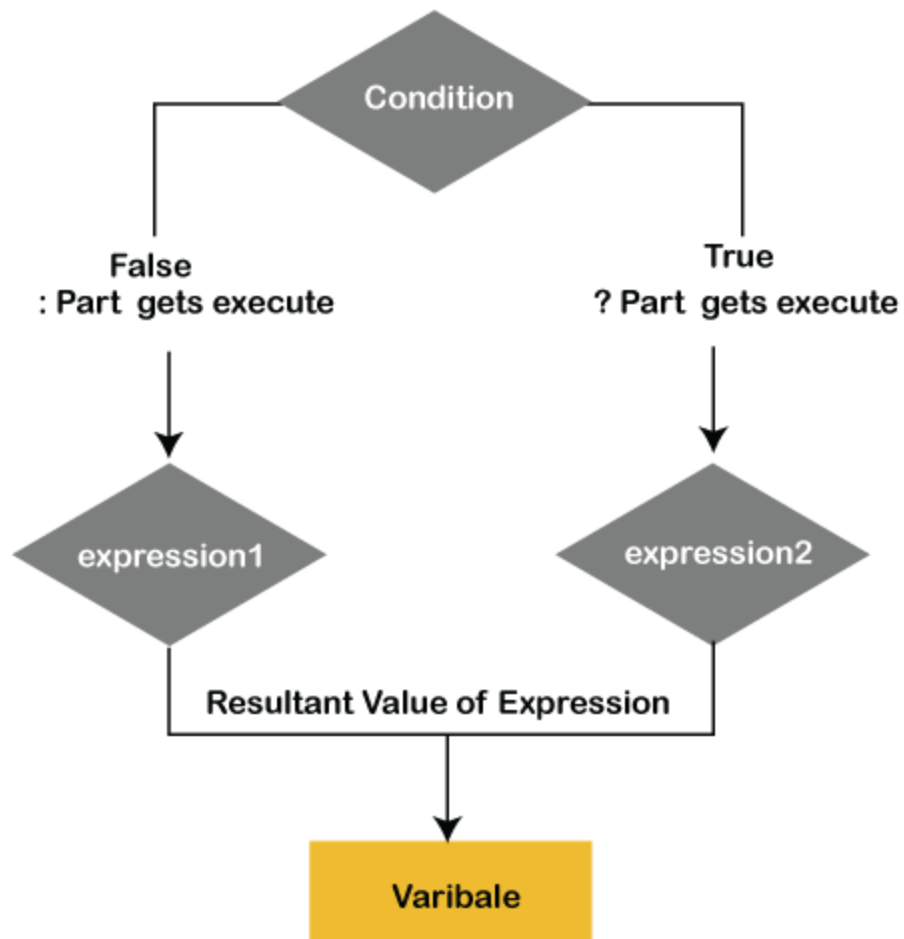

#### Syntax:

```
1. variable = (condition) ? expression1 : expression2  
   String result=(avg>=90)? "Grade A" : "fail";  
   Sop(result);
```

The above statement states that if the condition returns **true**, **expression1** gets executed, else the **expression2** gets executed and the final result stored in a variable.

Let's understand the ternary operator through the flowchart.

## Java Ternary Operator Example

1. **public class** OperatorExample{
2. **public static void** main(String args[]){
3. **int** a=2;
4. **int** b=5;
5. **int** min=(a<b)?a:b;
6. System.out.println(min);
7. }}

**Output:**

2

Another Example:

1. **public class** OperatorExample{
2. **public static void** main(String args[]){
3. **int** a=10;
4. **int** b=5;
5. **int** min=(a<b)?a:b;
6. System.out.println(min);
7. }}

### Output:

5

```
public class TernaryOperatorExample
{
public static void main(String args[])
{
int x, y;
x = 20;
y = (x == 1) ? 61: 90;
System.out.println("Value of y is: " + y);
y = (x == 20) ? 61: 90;
System.out.println("Value of y is: " + y);
}
}
```

### Output

```
Value of y is: 90
Value of y is: 61
```

### LargestNumberExample.java

```
public class LargestNumberExample
{
public static void main(String args[])
{
int x=69;
int y=89;
```

```

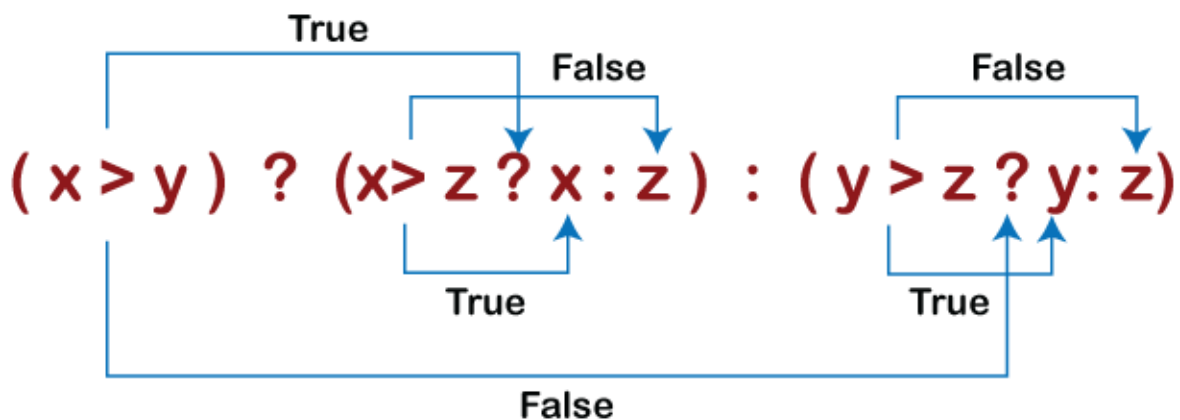

int z=79;
int largestNumber= (x > y) ? (x > z ? x : z) : (y > z ? y : z);
System.out.println("The largest numbers is: "+largestNumber);
}
}

```

## Output

```
The largest number is: 89
```

In the above program, we have taken three variables x, y, and z having the values 69, 89, and 79, respectively. The expression  $(x > y) ? (x > z ? x : z) : (y > z ? y : z)$  evaluates the largest number among three numbers and store the final result in the variable largestNumber. Let's understand the execution order of the expression.

First, it checks the expression  $(x > y)$ . If it returns true the expression  $(x > z ? x : z)$  gets executed, else the expression  $(y > z ? y : z)$  gets executed.

When the expression  $(x > z ? x : z)$  gets executed, it further checks the condition  $x > z$ . If the condition returns true the value of x is returned, else the value of z is returned.

When the expression  $(y > z ? y : z)$  gets executed it further checks the condition  $y > z$ . If the condition returns true the value of y is returned, else the value of z is returned.

## Java Assignment Operator

Java assignment operator is one of the most common operators. It is used to assign the value on its right to the operand on its left.

## Java Assignment Operator Example

1. **public class** OperatorExample{
2. **public static void** main(String args[]){
3. **int** a=10;
4. **int** b=20;
5. a+=4;//a=a+4 (a=10+4)
6. b-=4;//b=b-4 (b=20-4)
7. System.out.println(a);
8. System.out.println(b);
9. }}

### Output:

```
14
16
```

## Java Assignment Operator Example

1. **public class** OperatorExample{
2. **public static void** main(String[] args){
3. **int** a=10;
4. a+=3;//10+3
5. System.out.println(a);
6. a-=4;//13-4
7. System.out.println(a);
8. a\*=2;//9\*2
9. System.out.println(a);
10. a/=2;//18/2
11. System.out.println(a);
12. }}

## Java Assignment Operator Example: Adding short

1. **public class** OperatorExample{
2. **public static void** main(String args[]){
3. **short** a=10;
4. **short** b=10;
5. //a+=b;//a=a+b internally so fine

6. `a=a+b;`//Compile time error because 10+10=20 now int
7. `System.out.println(a);`
8. `}}`

### Output:

```
Compile time error
```

After type cast:

1. `public class` OperatorExample{
2. `public static void` main(String args[]){
3. `short` a=10;
4. `short` b=10;
5. `a=(short)(a+b);`//20 which is int now converted to short
6. `System.out.println(a);`
7. `}}`

### Output:

```
20
```

## Access Modifiers in Java

There are two types of modifiers in Java: **access modifiers** and **non-access modifiers**.

The access modifiers in Java specifies the accessibility or scope of a field, method, constructor, or class. We can change the access level of fields, constructors, methods, and class by applying the access modifier on it.

There are four types of Java access modifiers:

1. **Private:** The access level of a private modifier is only within the class. It cannot be accessed from outside the class.
2. **Default:** The access level of a default modifier is only within the package. It cannot be accessed from outside the package. If you do not specify any access level, it will be the default.

3. **Protected:** The access level of a protected modifier is within the package and outside the package through child class. If you do not make the child class, it cannot be accessed from outside the package.
4. **Public:** The access level of a public modifier is everywhere. It can be accessed from within the class, outside the class, within the package and outside the package.

There are many non-access modifiers, such as static, abstract, synchronized, native, volatile, transient, etc. Here, we are going to learn the access modifiers only.

## Understanding Java Access Modifiers

Let's understand the access modifiers in Java by a simple table.

Access Modifier	within class	within package	outside package by subclass only	outside package
Private	Y	N	N	N
Default	Y	Y	N	N
Protected	Y	Y	Y	N
Public	Y	Y	Y	Y
